【発明の詳細な説明】

【産業上の利用分野】本発明は、たとえばゲーム機や車 室内にて利用され、エンジン音等の最似音を発生する装 間に関する。

■ に乗りる。 【0002】 【従来の技術】 一般にゲーム機におけるカーレースにて

【従来の技術】一般にアーム機におするカーレー人にて 利用される車のエンジン音には音声合成を用いたよりリ アルな擬似音の発生が求められており、また実際の車室 内においても自車エンジン音とは異なる直接車のエンジ ン音に似せた擬似音科生装庫も提案されている。

【0003】たとえば、特別平5-11788号にて整 業される車能用機以エンジン音楽生装課は、シガライタ ーソケットからエンジンの回転数信号を検出し、あらか じか牛のエンジン帝を継令して音楽データとして記録し、50 てあるROM内のデータを回転数に応じて再生し、音声 として出力する構成をとっている。

[0004] このようなエンジン音の音声データはRO Mにて配線する他に任意の音声データをメモリカードに 配線しておき、所望のメモリカード選択によって好みの 音色を発生させるようを構成としても開示されている。 [0005]

(発明が禁決ようさする報酬) ところで、上記ROM サメモリカードは裏様なものとしてその記憶意義にも限 度があり、エンジン官の全配に数値の音声データを記録 しようとするときわめて大意義のメモリを必要とするた め、全回に数値の書声デーのサンプリングを似く別さ なければならず、結果として再生音が新切れたものとな リ、株に再生スピードがゆっくりな場合はその新教物音 所が不敗なものとってしまう。

【0006】また、エンジン問転数の上昇速度や下降速度の違いによって、あるいは一定回転数での具特間再生 たいまっても、それぞれ着色の変化を生ずるため、東実に生に近い音声を用きしようとすれば、各々の変化条件毎に音声データを記録しておかねばならずきわめて膨大な

記憶容量が必要となる。 [0007]そこで本発明は、配憶容量を少なく抑えな がら少ない音声データにて不自然さの目立たない擬似音 発生論塵を提出せんとするものである。

[8000]

「国籍を解決するための手段) 書データメモリ以下的た かデータとして開放を関するとしない。その取得データをその機能があった。 たデータとして開放を関するとしない。その取得データ 用まする用金物的部を相談人ためである。また記録者を のエングラセン、関連の返出人下列等と一次形式のの言を のエングラセン、関連の返出人下列等と一次形式ののことが し、その背を必要があったって一般であるとも し、その背を必要があるテンプで「発するととも し、その背を必要があるテンプで「発するととも し、その手を必要があるテンプで「発するととも し、その手を必要があるテンプで「発している」となっている。 ことには、書声である「発生の言葉を一般大したのである。 ことには、書声である「大きなどなどなどなどなどなどない」というである。

【作用】音声データメモリに記録した少ない音声データ にて不自然さの少ない比較的滑らかな広帯域の音声を再 生することができ、限られた音声データの構返し再生と 再生速度変更によって診切れ感の少ない音声となる。

[0010]

(54) PSEUDO SOUND GENERATING DEVICE

(57)Abstract:

PURPOSE: To provide a pseudo sound generating device generating smooth reproduced sounds with specific voice data while making voice data small and making a memory capacity for a voice data recording small.

CONSTITUTION: This device is provided with a reproducing control part 8 reproducing voice data recorded in the recording area of a voice data memory 7

in order of the recording and also reproducing them in reverse order of the recording. Then, the reproducing control part 8 can reproduce many kinds of patterns of voices with small data by reproducing adequately or continuously the same data with the changeover of reproducing directions and makes continuous reproduced sounds smooth. Moreover, a voice having no sound cutting feeling is reproduced or a voice having a wideband frequency is generated by providing a volume adjusting part 9 and a reproducing speed changing means 11 in the device.

CLAIMS

[Claim(s)]

[Claim 1] In the false sound generator reproduces the record data of the voice data memory which recorded the sound signal which carried out [voice / predetermined /, such as an engine sound, / raw] sound recording record or, which was modeled on raw voice, and it was made to generate a false sound by speech synthesis While carrying out sequential record as data which divided the voice data with which a predetermined period follows voice data memory for every record area of the The false sound generator characterized by having the playback control section which reproduces the voice data recorded on said voice data memory in order of record of record area, and reproduces the voice data of said this record area in order of reverse record, and reproduces predetermined voice.

[Claim 2] The false sound generator according to claim 1 which the voice recorded on said voice data memory is the voice data corresponding to the engine sound of a fixed engine speed mostly, and is characterized by carrying out repeat playback of the order of record, and the order of reverse record for the record data of said record area by said playback control section.

[Claim 3] The false sound generator according to claim 1 which the voice recorded on said voice data memory is the voice data corresponding to one engine sound at the time of an engine-speed rise or descent, and is characterized by reproducing the record data corresponding to one [said] engine sound in order of reverse record by said playback control section, and obtaining the engine sound of another side.

[Claim 4] The voice recorded on said voice data memory is the voice data corresponding to the engine sound at the time of the voice data corresponding to the engine sound of a fixed engine speed, an engine-speed rise, or descent mostly. While facing reproducing the voice data at the time of an engine-speed rise or descent, and the voice data of a fixed engine speed continuously, carrying out the lap of the playback change part and reproducing The false sound generator according to claim 1 to 3 characterized by equipping the playback in near [this.] a playback change with the sound-volume controller which accomplishes fade-out and fade-in processing respectively.

[Claim 5] From claim 1 which comes to have a reproduction speed modification means to change the rate which reproduces the voice data recorded on the record area of said voice data memory to a false sound generator according to

DETAILED DESCRIPTION

[Detailed Description of the Invention]

[0001]

[Industrial Application] This invention is used in a game machine or the vehicle

interior of a room, and relates to the equipment which generates false sounds, such as an engine sound.

[0002]

[Description of the Prior Art] The false sound generator modeled on the engine sound of a luxury car which it depends on the engine sound of the vehicle generally used in the car race in a game machine using speech synthesis, and generating of a real false sound is searched for, and is different from a self-vehicle engine sound also in the actual vehicle interior of a room is also proposed. [0003] For example, the false engine sound regenerative apparatus for mount proposed in JP,5-11788, A has taken the configuration which is reproduced according to an engine speed and outputs as voice the data in ROM which delects an engine engine-speed signal from a cigar-lighter socket, records a raw engine sound beforehand, and has been recorded as voice data. [0004] The voice data of such an engine sound is recorded in ROM, and also it records the voice data of arbitration on the memory card, and is indicated also as a configuration which generates a favorite tone by desired memory card selection. [0005]

[Problem(s) to be Solved by the Invention] by the way, since they need very

[0007] Then, this invention uses as an offer plug the false sound generator in

playback at a fixed rotational frequency.

which unnaturalness is not conspicuous with little voice data, stopping memory capacity few.

[0008]

[Means for Solving the Problem] While carrying out sequential record as data which divided the voice data with which a predetermined period follows voice data memory for every record area of the, it has the playback control section which reproduces the record data in order of record, and is reproduced in order of reverse record, and reproduces predetermined voice. Moreover, it faces carrying out [sound / engine] a record sound and carrying out continuation playback of each voice data corresponding to the engine sound at the time of engine-speed rise descent, and the time of a fixed engine speed, and while carrying out the lap of the playback change part and reproducing, the playback in near a change is equipped with the sound-volume controller which performs fade-out and fade-in processing respectively. Furthermore, it has a reproduction speed modification means to change the reproduction speed of the same voice data recorded on voice data memory.

[0009]

[Function] The voice of a comparatively smooth broadband with little unnaturalness can be reproduced with little voice data recorded on voice data memory, and it becomes voice with few feeling of a marks piece by the limited repetition playback and limited reproduction speed modification of voice data. [0010]

[Example] The most fundamental block diagram as an example of the false sound generator which this invention of drawing 1 is in the vehicle interior of a room of an automobile, and reproduces the engine sound of arbitration is shown. The power unit working state output section 1 For example, firing drault 1A which outputs the ignition putse signal from an engine ignition system, Pickup sensor 18 arranged at the engine gear section and the cigar-lighter socket of a car are equipped. Attachment electrode 1C which can extract an engine ignition noise, The signal corresponding to an engine speed by engine throttle opening

whenever [valve-opening / in which an output is possible] Sensor 1D. Or it is constituted by what can acquire the output signal corresponding to the rotation working state of an engine or a motor which is the power unit of cars, such as motor rotation sensor 1E which outputs the signal corresponding to the motor engine speed which is the power unit of an electric-type automobile. [0011] Here, although explained per configuration at the time of using attachment electrode object 1C, the voltage signal which the engine ignition noise superimposed is outputted to the electrode of a cigar-lighter socket, and this

voltage signal is supplied to attachment electrode object 1C by electrical connection. Since the high frequency noise other than an engine ignition noise to take out a part for an ignition noise as an engine speed signal through the signal filter circuit 2. (narrow width of face) which is not possible as a pulse of engine rotation for

(signal corresponding to an engine speed) is overlapped on this voltage signal. he is trying for the electrical signal acquired from attachment electrode object 1C [0012] Said signal filter circuit 2 can be judged to the signal of the width of face example, to be a noise, and the configuration which disregards the signal edge can be given as a filter function. For this filter function, it can give also by the data processing sections 3, such as a microcomputer mention later, for example, in the case of a four cycle 4-cylinder engine, the engine ignition periods at the time of 15000rpm (maximum engine speed) are 2msec(s). Since it becomes, that judge the signal not more than it to be the noise signal which is not possible, and the pulse edge which is a count processing object is disregard by that pulse period measurement at the time of such a signal input can carry out count processing only of the engine speed component signal. [0013] Moreover, while passing only a pulse signal as the noise-rejection technique mentioned above in said signal filter circuit 2, it is also possible it to carry out input process, using only the pulse signal which the data-processing section 3 is made to memorize the change property of a right engine ignition

signal, judges with a noise when the properties (whenever [pulse width and

pulse] the direction of-izing, variation, etc.) of the pulse signal actually inputted separate from a storage property, and fulfills a property as the signal corresponding to engine ignition.

[0014] A voltage signal including the engine ignition noise signal supplied by attachment electrode object 1G is inputted as a pulse signal corresponding to an engine speed by judgment processing of an input stage [in / for the signal filter circuit 2 which was mentioned above / through or the data-processing section 3]. The engine-speed detection in the data-processing section 3 counts the clock signal from the clock signal generating section 5 of high frequency for every input pulse signal cycle with a counter 4, and asks for an engine speed by the operation from that pulse period for every input pulse signal in operation part 6 based on this counted value.

[0015] In operation part 6, the memory address finger Sadanobu number corresponding to the engine-speed data for which it asked in this way defined beforehand is outputted, and the appointed address stored data of the voice data memory (ROM) 7 which memorized voice data is read. The address capacity is set up by whether it faces reproducing the voice data which a setup of the addressing signal in operation part 6 is made to correspond to the memory address of the voice data memorized to the voice data memory 7, and is memorized to the voice data memory 7 as a sound signal, and which makes engine-speed change carry out correspondence change smoothly. [0016] In this example, microphone sound recording was carried out [sound / of a high-class sports car / raw / engine] as voice data memorized to the voice data memory 7, and the sound recording data is subdivided and digitized for every engine-speed band with predetermined resolving power. That is, an accelerator is operated from an idling, the engine of a high-class sports car is gradually increased to a maximum engine speed [in / for an engine speed / actual transit], and it records as a signal A which shows the engine sound change accompanying the increment in an engine speed to drawing 2 recorded as

analog signalling frequency.

[0017] in this way, the recorded analog signalling frequency — for example, the number sec of several mf0sec – every — it divides and is made to assign and record on memory block of the voice data memory 7 in this division unit the sampling period which carries out sampling digitization of the analog signalling frequency A — dozens msec(s) - number sec every — it is set up on a still finer frequency, for example, a 32kHz signal cycle, for every division unit. [018] As \$\text{Short in drawing 3}, the memory area of the video data memory 7 is

requency, for example, a 32kHz signal cycle, for every d'histo unit.

[0018] As shown in drawing 3, the memory area of the voice data memory 7 is classified with a configuration called the memory block 7A, 7B, and 7C corresponding to said division unit. Seven A001 which memorizes the sampling data for every still shorter periods, such as said 32kHz signal, for each memory-block 7A etc., seven A002, and record area (address) called seven A003 are set up. It is made to memorize as voice data which carried out sampling digital conversion of said analog signalling frequency to this record area.

[0019] The voice data memorized to the voice data memory 7 is read from memory block of the division unit part corresponding to an input engine speed in the data-processing section 3, and it is outputted to the playback control section.

are date-processing section 5, and it is outputed to the payocks control section 8 in order to reproduce as a frequency-characteristics signal of a division unit part by composition of the voice data memorized to each address in the memory block.

[0020] For example, since the voice data recorded on each address of memory-

block.

[0020] For example, since the voice data recorded on each address of memory-block 7A of the voice data memory 7 is memorized as fragmentation digital data according the analog signalling frequency property of a division unit part that drawing 2 corresponds, to a sampling period, the digital data read from each address of this memory-block 7A is reproducible with having been easily shown in drawing 2 to the same analog signalling frequency by carrying out D/A conversion one by one a sampling period and the same conversion period.

[0021] Thus, the sound signal generated by the playback control section 8 if the

conversion one by one a sampling period and the same conversion period.

[0021] Thus, the sound signal generated by the playback control section 8 if the sounding bodies 10, such as a loudspeaker, can be made to utter through the sound-volume controller 9 and the input signal to the data-processing section 3 is continuing being inputted at a fixed rotational frequency II can be made to utter

as a regenerative signal of the division unit part shown in drawing 2 of the frequency which ****ed in the rotational frequency. In the data-processing section 3, the address signal (working state indication signal) of the corresponding division unit part by frequency (rotational frequency) change of an input signal is outputted to the memory section 7. The tone change very near the raw engine sound corresponding to the frequency band (engine speed) of an input signal can be generated by read-out and sound signal generation of the corresponding voice data from memory block. In addition, the playback control section 8 is constituted including a reproduction speed modification means 11 to change the reproduction speed (frequency) of the voice data of the voice data memory 7. [0022] Although an engine sound is easily reproducible by making the voice data memory 7 memorize a desired engine sound beforehand by the fundamental configuration explained above, when making a smooth engine sound utter to change of an input signal more or asking for an actually near engine sound, it explains below per concrete operation of this invention for lessening capacity of the voice data memory 7.

[0023] Drawing 4 explains the regenerative function by the playback control section 8 of this invention which makes voice data memory 7 a smaller capacity, and enabled it to reproduce an engine sound. As shown in drawing 3, for carrying out division storage by the same memory-block method altogether, capacity becomes large extremely to all the bands of an engine speed. Since a division unit must be divided with a finer time Interval in order to obtain a smooth tone change especially, and it will become very [in capacity] expensive, comparatively with a narrow band data storage The playback of a continuation sound based on this stored data is reproduced in the repeat of the order of record of the data in record area, and the order of reverse record. [0024] Namely, sequential record of the voice data for about several seconds corresponding to the engine sound of an engine speed fixed to memory-block 7A of the voice data memory 7 shown in drawing 3 at a predetermined engine speed is carried out at the record area seven A001 within the block - 7Annn. So that the

record gestalt may be known in drawing 4 displayed as a wave of a sound signal in simulation A difference arises not a little in the tone which includes the sound volume by the data of the beginning of the record area of memory-block 7A, and the last data. If it reproduces repeatedly in order of the record which carried out sequential record of the voice data of this memory-block 7A at the record area seven A001 - 7Annn and prolonged playback is performed Although distortion will surely arise and the sense of incongruity and displeasure of a playback sound like a sound piece will be given for every playback repeat of the at the time of the playback which returns from playback of 7Annn(s) to seven A001 In this invention, after reproducing in order of record to the record area seven A001 -7Annn, it reproduces continuously in order of the reverse record in seven A001 direction from 7Annn(s). Continuation playback which used the voice data of this memory-block 7A again by repeat playback of the order of record from seven A001 and the order of reverse record from 7Annn(s) is performed after that. [0025] Therefore, the voice data of memory-block 7A can generate smooth voice without distortion of a sound by the repeat of the order reverse playback by playback control section 8 like the arrow head shown in drawing 4 from the

playback control section 8 like the arrow head shown in drawing 4 from the record area within the block. [0026] That is, since the voice data recorded on the record area of memory-block 7A serves as change of the data in alignment with a motion smooth in the range, if it reproduces in the seven A001 direction in order of reverse record continuously after ending by 7Annn at the time of repeat playback It becomes

If it reproduces in the seven A001 direction in order of reverse record continuously after ending by 7Annn at the time of repeat playback it becomes possible to reproduce in order of the record area which recorded the smooth change data which always adjoin each other, and a playback sound with displeasure like a sound piece is prevented, and it becomes reproducible [a smooth continuation sound].

[0027] Moreover, the voice data corresponding to the engine sound of a fixed engine speed which was recorded on memory-block 7A is 1000rpm, 2000rpm, and 3000rpm. If it records on memory block which sets a predetermined engine speed as arbitration like, and is different for two or more fixed engine speeds of

every Smooth playback of the engine sound corresponding to an input engine speed is similarly attained by using the same playback approach as the above in the voice data of memory block chosen corresponding to the input engine speed. [0028] Although the playback approach of the voice data of the record area within such memory block enables smooth playback without the sound piece at the time of continuation playback, it is applicable also to memory space compression of the playback voice data at the time of the rise of an engine speed, and descent. [0029] That is, if the voice data at the time of an engine-speed rise is recorded on the record area of memory-block 7B, and this is reproduced in order of the record or 7Bnnn(s) from the record area seven B001, the voice corresponding to the time of an engine-speed rise is reproducible, and if it reproduces in order of the

or continuation payeack, it is applicable also to memory space compression or the playback votice data at the film of the rise of an engine speed, and descent. [0029] That is, if the voice data at the time of an engine-speed rise is recorded on the record area of memory-block 7B, and this is reproduced in order of the record to 7Bnnn(s) from the record area seven B001, the voice corresponding to the time of an engine-speed rise is reproducible, and if it reproduces in order of the reverse record to seven B001 from 7Bnnn(s), it will become possible further to reproduce the voice corresponding to the time of engine-speed descent. [0030] By reproducing the property data corresponding to the ascending curve of the frequency wave of voice data which becomes high in order of reverse record with an engine-speed rise, it becomes the regenerative signal of a downward curve which becomes low gradually, this serves as voice data at the time of extual engine-speed descent, and playback of similar data as a result, and this can be reproduced as an engine sound equivalent to the time of descent.

with an engine-speed rise, it becomes the regenerative signal of a downward curve which becomes low gradually, this serves as voice data at the time of actual engine-speed descent, and playback of similar data as a result, and this can be reproduced as an engine sound equivalent to the time of descent. [0031] Therefore, if only the data of either the voice data at the time of an engine-speed rise or the voice data at the time of descent are recorded on memory block, it becomes possible to be able to reproduce the voice for record by playback of the order of record, and to reproduce voice equivalent to the voice of another side by playback of the order of reverse record, and memory space can be simply made into one half. In addition, when rise descent is performed continuously, it switches and can consider as the smooth playback in which a sound piece is not conspicuous with the corresponding order reverse playback change in the storage area in a point. [0032] Based on the engine-speed signal searched for by the data-processing section 3, the rise downward change condition of the engine speed is judged by

the playback control section 8, and selection of the order playback of record corresponding to rise descent of such an engine speed and the order playback of reverse record is performed by specifying the read-out sequence (addressing sequence) to the voice data memory 7, and reproducing. However, although the change condition of an engine speed is judged in the data-processing section 3 and you may make it specify playback sequence by the playback control section 8 based on the judgment result, in the playback control section 8, digital data is function generated as a sound signal. 100331 Moreover, the sound volume of the false engine sound which should

changed into an analog signal by the input of such voice data, and it also has the generate the sound signal generated by the playback control section 8 by the sound-volume controller 9 is adjusted, the changing point judging of the engine speed according I this sound-volume controller 9 I to the data-processing section 3 -- especially -- rise downward data and fixed engine-speed data -- switching -volume control in the neighborhood -- carrying out -- the -- it constitutes so that switch, and may make the fade-out in the neighborhood, and fade-in processing. it may switch, the marks piece condition of the unnatural voice in a point may be ease and it may reproduce as change of a smooth sound. 100341 For example, supposing it records the voice data corresponding to the

engine sound of a fixed engine speed on memory-block 7A of the voice data memory 7 and records the voice data corresponding to the engine sound at the time of an engine-speed rise on memory-block 7B With the engine-speed rise in 7B, in the situation that the input rotational frequency changed to the fixed rotational frequency field in 7A Alike in if the change condition is judged in the

data-processing section 3, the voice data of 7A and 7B switches to the playback timing which switched and got mixed up at the point and coincidence playback (playback which prepares a lap part) near a point is performed each regenerative signal -- receiving -- the -- switching -- as volume control in the neighborhood -each - fade-out and fade-in processing (while making one sound volume small and muffling it gradually) A marks piece is lessened by hybrid processing,

performing processing which enlarges sound volume of another side gradually from a silence condition similarly.

[0035] As opposed to the playback time amount t corresponding to [as this showed by drawing 5] input rotational frequency change the relation of the sound volume dB It faces shifting to a fixed rotational frequency from the rise of an engine speed. You can switch and the rise sound from memory-block 7B corresponding to each and the fixed sound from memory-block 7A can make it generate as the natural relation by fade-out and fade-in processing in the lap part in the neighborhood. It switches, a point fades and ****** of playback data heromes unclear

[0036] Moreover, by changing the reproduction speed (playback frequency) of the voice data currently recorded on the record area of memory-block 7A based on the height judging of the engine speed in the data-processing section 3, and generaling the voice of the large engine-speed range using the same voice data, the reproduction speed modification means 11 in the playback control section 8 is constituted so that memory space may be lessened.

generating the voice of the large engine-speed range using the same voice data, the reproduction speed modification means 11 in the playback control section 8 is constituted so that memory space may be lessened.

[0037] this – for example, memory-block 7A – 1000rpm a law, if the voice data corresponding to the engine sound of an engine speed is recorded It is 1000rpm by reproducing the voice data of record area with the same reproduction speed as the record liming. Although considerable voice is generable Are reproducible as a playback wave which produces the voice which resembled the engine sound corresponding to the engine speed of a high rotation region more by bringing this reproduction speed forward. If the reproduction speed is beforehand set as multistage based on the input frequency result of an operation in the data-processing section 3, it will become possible to generate the voice corresponding to a large engine-speed band in reproduction speed modification of little voice data.

[0036] Moreover, as drawing 6 showed, record the master data as shown in this drawing (A) as rise sound data, and the playback sound when reproducing by the playback time amount to (basic reproducion speed) is received. Are reproducible

as voice with a frequency higher than the original speech frequency which the master data has seemingly by reproducing the same voice data with reproduction speed quicker than basic reproduction speed called playback time amount t1<t0 as shown in this drawing (B). If the same voice data is reproduced with the reproduction speed conversely later than basic reproduction speed called playback time amount t2>t0 like, are reproducible as voice with a frequency lower than original speech frequency, moreover, this drawing (C) - By setting up such reproduction speed suitably as a result, and reproducing with the reproduction speed corresponding to input rotational frequency rate of change (whenever f acceleration-and-deceleration 1) It becomes possible to reproduce with little voice data, without memorizing the voice equivalent to the engine sound corresponding to the acceleration and deceleration of an engine speed as all data corresponding to each acceleration and deceleration. [0039] Such regeneration becomes possible [realizing in circuitry with very little amount of data together with the playback approach of the voice data shown by drawing 41. [0040]

[Effect of the Invention] The false sound generator which becomes this invention as mentioned above can lessen the amount of voice data to record, can reproduce wide range voice, and becomes possible [lessening memory space] from performing playback in the order of reverse record and carrying out voice playback of little voice data recorded on the record area of voice data memory with playback in the order of record. Moreover, are reproducible as smooth voice in which the continuity of a playback sound does not have a feeling of a marks piece, either. Switch and it considers as a smooth thing by the fade-out in the neighborhood, and fade-in processing, relation of the voice data furthermore recorded — the — It becomes possible to generate the frequency false sound of the broadband by little voice data by frequency modification of the playback sound by voice data reproduction speed modification in further predetermined

memory, and the false sound generator which can generate voice variegated at memory space small also as the whole can be offered.
